## ASTRONOMIA NOVA

Original title page and translation of title .....	1–4
Dedication to Rudolph II .....	5
Epigrams .....	10
Introduction .....	17
Synoptic Table .....	38
Summaries of the Individual Chapters .....	41
Kepler's Index .....	67

## PART 1: ON THE COMPARISON OF HYPOTHESES

<b>Chapter 1:</b> On the distinction between the first motion and the second or proper motions; and in the proper motions, between the first and the second inequality. ....	75
--	----

**Chapter 2:** On the first and simple equivalence, that of the eccentric and the concentric with an epicycle, and their physical causes. . . . . 81

**Chapter 3:** On the equivalence and unanimity of different points of observation and of hypotheses, for laying out one and the same planetary path. . . . . 87

**Chapter 4:** On the imperfect equivalence between a double epicycle on a concentric, or eccentric-epicycle, and equant on an eccentric. . . . . 89

**Chapter 5:** The extent to which this arrangement of orbs, using either an equant or a second epicycle, while remaining entirely one and the same (or very nearly one and the same), can present different phenomena at one and the same instant, according to whether the planets are observed at mean or at apparent opposition to the sun. . . . . 94

**Chapter 6:** On the equivalence of the hypotheses of Ptolemy, Copernicus, and Brahe, by which they demonstrated the second inequality of the planets, and how each one varies when accommodated to the sun's apparent position and when accommodated to its mean position. . . 105

**PART 2: ON THE FIRST INEQUALITY OF THE STAR MARS,  
IN IMITATION OF THE ANCIENTS**

**Chapter 7:** The circumstances under which I happened upon the theory of Mars. . . . . 133

**Chapter 8:** Tycho Brahe's table of observed and computed observations of Mars's oppositions to the line of the sun's mean motion, and an examination thereof. . . . . 136

**Chapter 9:** On referring the ecliptic position to the circle of Mars. . . 141

**Chapter 10:** Consideration of the observations themselves, with which Tycho Brahe hunted for the moments of opposition to the mean sun. 145

**Chapter 11:** On the diurnal parallaxes of the star Mars. . . . . 149

**Chapter 12:** Investigation of Mars's Nodes. . . . . 160

**Chapter 13:** Investigation of the inclination of the planes of the ecliptic and of the orbit of Mars. . . . . 164

**Chapter 14:** The planes of the eccentrics are non-librating. . . . . 172

**Chapter 15:** Reduction of observed positions at either end of the night to the line of the sun's apparent motion. . . . . 174

**Chapter 16:** A method of finding a hypothesis to account for the first inequality. . . . . 184

**Chapter 17:** A superficial investigation of the motion of the apogee and nodes. . . . . 202

**Chapter 18:** Examination of the twelve acronychal positions using the hypothesis we have found. . . . . 205

**Chapter 19:** A refutation, using acronychal latitudes, of this hypothesis constructed according to the opinion of the authorities and confirmed by all the acronychal positions. . . . . 208

**Chapter 20:** Refutation of the same hypothesis through observations in positions other than acronychal. . . . . 212

**Chapter 21:** Why, and to what extent, may a false hypothesis yield the truth? . . . . . 217

Conclusion of Part 2 . . . . . 221

PART 3: INVESTIGATION OF THE SECOND INEQUALITY;  
 THAT IS, OF THE MOTIONS OF THE SUN OR EARTH;  
 OR THE KEY TO A DEEPER ASTRONOMY,  
 WHEREIN THERE IS MUCH  
 ON THE PHYSICAL CAUSES OF THE MOTIONS.

**Chapter 22:** The epicycle, or annual orb, is not equally situated about the point of equality of motion. . . . . 225

**Chapter 23:** From the knowledge of two distances of the sun from the earth and of the zodiacal positions and the sun's apogee, to find the eccentricity of the sun's path (or the earth's, for Copernicus). . . . . 231

**Chapter 24:** A clearer proof that the epicycle or annual orb is eccentric with respect to the point of uniformity. . . . . 233

**Chapter 25:** From three distances of the sun from the center of the world, with known zodiacal positions, to find the apogee and eccentricity of the sun or earth. . . . . 239

**Chapter 26:** Demonstration from the same observations that the epicycle is eccentric with respect to the point of attachment or axis, and that the annual orb (and so also the earth's path around the sun, or the sun's around the earth) is eccentric with respect to the body of the sun or earth, with an eccentricity just half that which Tycho Brahe found through equations of the sun's motion. . . . . 241

**Chapter 27:** From four other observations of the star Mars outside the acronychal situation but still in the same eccentric position, to demonstrate the eccentricity of the earth's orb, with its aphelion and the ratio of the orbs at that place, together with the eccentric position of Mars on the zodiac. . . . . 254

**Chapter 28:** Assuming not only the zodiacal positions of the sun, but also the sun's distances from the earth found using an eccentricity of 1800, through a number of observations of Mars at the same eccentric position, to see whether by unanimous consent the same distance of Mars

from the sun, and the same eccentric position, are elicited. By which argument, it will be confirmed that the solar eccentricity of 1800 is correct, and was properly assumed. ....	258
<b>Chapter 29:</b> A Method of Deducing the Distances of the Sun and Earth from the Known Eccentricity .....	264
<b>Chapter 30:</b> Table of the distance of the sun from the earth and its use .....	269
<b>Chapter 31:</b> That the bisection of the sun's eccentricity does not perceptibly alter the equations of the sun set out by Tycho; and concerning four ways of computing them. ....	273
<b>Chapter 32:</b> The power that moves the planet in a circle diminishes with removal from its source. ....	275
<b>Chapter 33:</b> The power that moves the planets resides in the body of the sun. ....	278
<b>Chapter 34:</b> The body of the sun is magnetic, and rotates in its space. ....	285
<b>Chapter 35:</b> Whether the motion from the sun, like its light, is subject to privation in the planets through occultations. ....	290
<b>Chapter 36:</b> By what measure the motive power from the sun is attenuated as it spreads through the world. ....	292
<b>Chapter 37:</b> How the power moving the moon may be constituted. ....	296
<b>Chapter 38:</b> Besides the common motive force of the sun, the planets are endowed with an inherent force [ <i>vis insita</i> ], and the motion of each of them is compounded of the two causes. ....	299
<b>Chapter 39:</b> By what path and by what means the powers seated in the planets ought to move them, in order that the planet's circular orbit, such as is commonly thought to exist, be brought about in the aethereal air. ....	301
<b>Chapter 40:</b> An imperfect method for computing the equations from the physical hypothesis, which nonetheless suffices for the theory of the sun or earth. ....	309

PART 4: INVESTIGATION OF THE TRUE MEASURE  
OF THE FIRST INEQUALITY  
FROM PHYSICAL CAUSES  
AND THE AUTHOR'S OWN IDEAS

<b>Chapter 41:</b> A trial examination of the apsides and eccentricity, and of the ratio of the orbs, using the observations recently employed, made at locations other than opposition with the sun, with, however, a false assumption. ....	319
---	-----

**Chapter 42:** Through several observations at places other than the acronychal position, with Mars near aphelion, and again several others with Mars near perihelion, to find the exact location of the aphelion, the correction of the mean motion, the true eccentricity, and the ratio of the orbs. .... 322

**Chapter 43:** On the defect in the equations accumulated by bisection of the eccentricity and the use of triangular areas, on the supposition that the planet's orbit is perfectly circular. ....332

**Chapter 44:** The path of the planet through the ethereal air is not a circle, not even with respect to the first inequality alone, even if you mentally remove the Brahean and Ptolemaic complex of spirals resulting from the second inequality in these two authors. ....336

**Chapter 45:** On the natural causes of this deflection of the planet from the circle: first opinion examined. .... 339

**Chapter 46:** How the line of the planet's motion can be described from the opinion of Chapter 45, and what its properties are. ....342

**Chapter 47:** An attempt is made to find the quadrature of the oval-shaped plane which Chapter 45 produced, and which we have been busying ourselves to describe in Chapter 46; and through the quadrature, a method of finding the equations. .... 349

**Chapter 48:** A method of computing the eccentric equations by a numerical measure and division of the circumference of the ovoid described in Ch. 46. .... 358

**Chapter 49:** A critical examination of the previous method for the equations, and a more concise method, based upon the principles constituting the oval in the opinion of Chapter 45. .... 365

**Chapter 50:** On six other ways by which an attempt was made to construct the eccentric equations. .... 370

**Chapter 51:** Distances of Mars from the sun are explored and compared, at an equal distance from aphelion on either semicircle; and at the same time the trustworthiness of the vicarious hypothesis is explored. ...379

**Chapter 52:** Demonstration from the observations of Chapter 51 that the planet's eccentric is set up, not about the center of the sun's epicycle, or the point of the sun's mean position, but about the actual body of the sun; and that the line of apsides goes through the latter rather than the former. ....393

**Chapter 53:** Another method of exploring the distances of Mars from the sun, using several contiguous observations before and after acronychal position: wherein the eccentric positions are also explored at the same time. ....396

**Chapter 54:** A more accurate examination of the ratio of the orbs. ..403

**Chapter 55:** From the observations of Chapters 51 and 53, and the ratio of the orbs of Chapter 54, it is demonstrated that the hypothesis seized upon in Chapter 45 is in error, and makes the distances at the middle elongations shorter than they should be. . . . . 405

**Chapter 56:** Demonstration from the observations already introduced, that the distances of Mars from the sun are to be chosen as if from the diameter of the epicycle. . . . . 407

**Chapter 57:** By what natural principles the planet may be made to reciprocate as if on the diameter of an epicycle. . . . . 410

**Chapter 58:** In what manner, while the reciprocation discovered and demonstrated in Chapter 56 holds good, an error may nevertheless be introduced in a wrongheaded application of the reciprocation, whereby the path of the planet is made puff-cheeked. . . . . 428

**Chapter 59:** Demonstration that when Mars reciprocates on the diameter of an epicycle, its orbit becomes a perfect ellipse; and that the area of the circle measures the sum of the distances of points on the circumference of the ellipse. . . . . 431

**Chapter 60:** A method, using this physical—that is, authentic and perfectly true—hypothesis, of constructing the two parts of the equation and the authentic distances, the simultaneous construction of both of which was hitherto impossible using the vicarious hypothesis. An argument using a false hypothesis. . . . . 444

PART 5: ON THE LATITUDE

**Chapter 61:** An examination of the position of the nodes. . . . . 453

**Chapter 62:** An examination of the inclination of the planes. . . . . 455

**Chapter 63:** Physical hypothesis of the latitude. . . . . 459

**Chapter 64:** Examination of the parallax of Mars through the latitudes. . . . . 465

**Chapter 65:** Investigation of the maximum latitude in both regions: in conjunction as well as opposition with the sun. . . . . 467

**Chapter 66:** The maximum excursions in latitude do not always occur at opposition to the sun. . . . . 469

**Chapter 67:** From the positions of the nodes and the inclination of the planes of Mars and the ecliptic, it is demonstrated that the eccentricity of Mars takes its origin, not from the point of the sun’s mean position (or, for Brahe, the center of the sun’s epicycle), but from the very center of the sun. . . . . 472

**Chapter 68:** Whether the inclinations of the planes of Mars and the ecliptic are the same in our time and in Ptolemy’s. Also, on the latitudes of the ecliptic and the nonuniform circuit of the nodes. . . . . 475

**Chapter 69:** A consideration of three Ptolemaic observations, and the correction of the mean motion and of the motion of the aphelion and nodes. .... 481

**Chapter 70:** Consideration of the remaining two Ptolemaic observations, in order to investigate the latitude and ratio of the orbs at the time of Ptolemy. .... 496

Appendix A: Observations Used by Kepler ..... 501

Appendix B: On the Table of Oppositions in Chapter 15 ..... 511
